A photograph of Herbert Simon, a pioneer in artificial intelligence, standing in front of a chalkboard. The chalkboard is filled with handwritten mathematical problems and diagrams. On the left, it says "Solve $x+3=4$ we do $x+3-3=4-3$ why can we do so? why -3 ?", "to find a number substituted we get", and "Solve:". On the right, there is a flowchart with a diamond-shaped decision node labeled "yes/no" and a box labeled "Assimilation". At the bottom right, it says "KDB" and "AAA".

"It is not my aim to surprise or shock you – but the simplest way I can summarize is to say that there are now in the world machines that think, that learn and that create. Moreover, their ability to do these things is going to increase rapidly until – in a visible future – the range of problems they can handle will be coextensive with the range to which human mind has been applied." (Herbert Simon 1957)

I'd like the books and the hats

I will take the books and hats

I really need the books and at least one other object

Ok, you can have one book and one ball

If I can have all the books, I can leave you the rest

Deal

You can have the ball if I can have everything else

No can't do that the ball is not going to give me anything

I need the hats and you can have the rest

Deal

Great! Thank you!

OpenAI's transformer-based model

OpenAI on GPT-2

"We've trained a large-scale unsupervised language model which generates coherent paragraphs of text, achieves state-of-the-art performance on many language modeling benchmarks, and performs rudimentary reading comprehension, machine translation, question answering, and summarization—all without task-specific training."

"Due to concerns about large language models being used to generate deceptive, biased, or abusive language at scale, we are only releasing a much smaller version of GPT-2 along with sampling code. We are not releasing the dataset, training code, or GPT-2 model weights."

- **PR Focus** - reporters were given early information
- **Gatekeeping** - malicious uses were hypothesized and we have no way of testing
- **Misdirected** - not releasing affects researchers more than malicious actors due to the model price
- **Dual use** - OpenAI did not discuss dual-use technology

13 KLN = Researcher(name = 'Kristoffer L Nielbo', \
14                 title = 'Associate professor', \
15                 areas = ['Humanities Computing', 'Culture Analytics', 'eScience'])
16
17 KLN.says_hello()

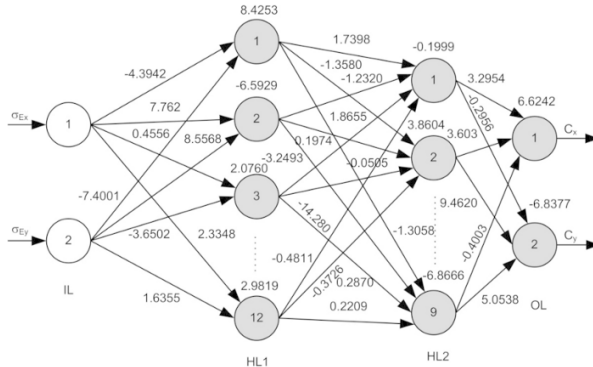

```

Software 1.0

- each line 1-17 produce a behavior (do this, then this ...)
- utilizes a programming language, e.g., Python, C++
- human-friendly code

Software 2.0

- specify some goal on the behavior and write a solution architecture
- search and optimization problem
- abstract weights in a neural network

Just a machine that learns

Machine learning emerged from AI - **build a computer system that automatically improves with experience**

- application requires pattern recognition in large data
- application is too complex for a manually designed algorithm
- application needs to customize its operational environment after it is fielded

Mitchell's well-posed learning problem

A computer program is said to learn from experience E with respect to some task T and some performance measure P , if its performance on T , as measured by P , improves with experience E

Historically, ML is “just” part of the **industrial age's efforts towards perfecting task automation**

Vikram Bisen

Though, nowadays many tasks can be independently performed by AI-enabled devices, systems or machines without the help of humans. But developing such machines is not possible without the help of humans. So, Human-in-the-Loop or HITL is a model or concept require human interaction.

Human-in-the-Loop is a process where optimization of learning algorithms requires human intervention

- algorithms are not understanding the input
- when data input is interpreted incorrectly
- algorithms do not know how to perform the task
- to make the machine learning model more accurate
- when the cost of errors is too high in development
- when the data is rare or not available

Humanities research meets machine learning

As a **consequence of the data surge**, we are (also) “jumping the automation bandwagon”

– plus **theoretical innovations that rely on ML/DL** (e.g., lexical → compositional semantics)

Inherent challenges in data and users

- data are unstructured, heterogeneous, need normalization, low resource varieties
- users lack of computational literacy, gap between technology and domain

knowledge

Types of problems solved by ML:

- initially ML was the solution to a(-ny) research problem
- increasingly, ML solves auxiliary tasks related to automation

Confusion matrix for binary classification task (credit: Towards Data Science)

Prediction Accuracy (ACC): $\frac{TP+TN}{TP+TN+FP+FN} = \frac{3+4}{3+4+2+1} = 0.7$

Precision (P) = $\frac{TP}{TP+FP} = \frac{3}{3+2} = 0.6$

Recall (R) = $\frac{TP}{TP+FN} = \frac{3}{3+1} = 0.75$

Precision: fraction of retrieved instances that are relevant

$$P = \frac{TP}{TP + FP}$$

Recall: fraction of relevant instances that are retrieved

$$R = \frac{TP}{TP + FN}$$

P and R are inversely related. Identify balance through a Precision-Recall curve.

“Suppose we want to determine the risk that a person is a carrier for a disease Y , and suppose that a higher fraction of women than men are carriers. Then our results imply that in any test designed to estimate the probability that someone is a carrier of Y , at least one of the following undesirable properties must hold: (a) the test's probability estimates are systematically skewed upward or downward for at least one gender; or (b) the test assigns a higher average risk estimate to healthy people (non-carriers) in one gender than the other; or (c) the test assigns a higher average risk estimate to carriers of the disease in one gender than the other. The point is that this trade-off among (a), (b), and (c) is not a fact about medicine; it is simply a fact about risk estimates when the base rates differ between two groups”

Assume differing base rates, $Pr_a(Y = 1) \neq Pr_b(Y = 1)$, and an imperfect learning algorithm, $C \neq Y$, then you cannot simultaneously achieve:

Precision parity $Pr_a(Y = 1 \mid C = 1) = Pr_b(Y = 1 \mid C = 1)$

True positive parity $Pr_a(C = 1 \mid Y = 1) = Pr_b(C = 1 \mid Y = 1)$

False positive parity $Pr_a(C = 1 \mid Y = 0) = Pr_b(C = 1 \mid Y = 0)$

bias in computer systems

preexisting

originates in social institutions, practices, and attitudes → computer systems embody biases that exist independently, and usually prior to the creation of the system

technical

product of technical constraints or consideration due to limitations of computer tools (e.g., databases, hardware), decontextualized algorithms, random number generation, and formalization of human constructs

emergent

arises in a context of use with real users as a result of changing societal knowledge, population, or cultural values (e.g., new societal knowledge, mismatch between user and system design)

“We conclude by suggesting that freedom from bias should be counted among the select set of criteria – including reliability, accuracy, and efficiency – according to which the quality of systems in use in society should be judged”

fairness \Rightarrow parity

“fairness” is probabilistically defined as *parity*

- many parity definitions: demographic, accuracy, true positive, predictive value, **precision**, ...
- Fairness and machine learning – Limitations and Opportunities
- Decisions should be in some sense **probabilistically independent of sensitive features values** (such as gender, race)

ensure that common measures of predictive performance are equal across all classes

$$Pr_{male}(Y = 1 \mid C = 1) = Pr_{female}(Y = 1 \mid C = 1)$$

$$0.11 \neq 0.89$$

low: the titanic survival rate classifier does not achieve **precision parity**

Impossibility results revisited

X is a dataset that contains feature on an individuals (e.g., income level, age)

- X incorporates all sorts of measurement biases

A is a sensitive attribute (e.g., ethnicity, religion, gender)

- A is often unknown, ill-defined, misreported, or inferred

Y is the true outcome (i.e., ground truth, e.g., survival)

C is an ML algorithm that uses X and A to predict the value of Y (e.g., whether a passenger survives)

– the sensitive attribute A divides the population into two groups a (e.g., male) and b (e.g., female)

– the ML algorithm C outputs 0 (e.g., predicts dead) and 1 (e.g., predicts survive)

– the true outcome Y is 0 (e.g., dead) and 1 (e.g., survive)

then you cannot simultaneously achieve,

$$Pr_a(Y = 1 \mid C = 1) = Pr_b(Y = 1 \mid C = 1)$$

$$Pr_a(C = 1 \mid Y = 1) = Pr_b(C = 1 \mid Y = 1)$$

$$Pr_a(C = 1 \mid Y = 0) = Pr_b(C = 1 \mid Y = 0)$$

or, precision parity and equalized odds are not simultaneously possible

How to achieve parity?

The trade-off among P, TP and FP is simply a fact about risk estimates when the base rates differ between two or more groups!

Simple models allow for fine-grained control on the degree of fairness, often at a small cost in terms of accuracy

Demographic Parity, also called Independence, Statistical Parity, is one of the most well-known criteria for fairness.

$$C \text{ is independent of } A \text{ if } Pr_a(C = c) = Pr_b(C = c) \forall c \in \{0, 1\}$$

Solutions

LIME, an algorithm that can explain the predictions of any classifier or regressor in a faithful way, by approximating it locally with an interpretable model (source: 1602.049338:arXiv)

Technical

- preprocessing the data to make it less biased
- learn fair representations that encode data while obfuscating sensitive attributes
- penalize the algorithm to encourage it to learn fairly
- allow the sensitive attributes during training, but not during inference time
- causal inference

Policy

- regulations (e.g., GDPR)
- laws that grant users the right to a logical explanation of how an algorithm uses our personal data
- explainability at the level of predictive performance

Neurons

Basic computational unit of a neural network

A neuron takes inputs, x_1 , x_2 , does *some math on them*, and generates an output, y

The input is weighted

$$x_1 \rightarrow x_1 \times w_1$$

$$x_2 \rightarrow x_2 \times w_2$$

then added with a bias

$$(x_1 \times w_1) + (x_2 \times w_2) + b$$

and finally passed through an activation function

$$y = f(x_1 \times w_1 + x_2 \times w_2 + b)$$

A word on the activation functions

The sigmoid activation function “squashes” an unbounded $(-\infty, +\infty)$ to a bounded $(0, 1)$ set. Computationally simpler activation functions, such as rectifiers, have to a large extent replaced sigmoids.

Neurons in a network

An artificial neural network is just a set of neurons wired together (typically) in a layered structure.

Feedforward neural network with one hidden layer of size m . A hidden layer is any layer between the input and output. Hidden layers perform transformations on the input or previous hidden layers. A network can have many hidden layers.

A neural network can have any number of neurons and layers. *Deep* in deep learning just refers to representations learned in multi-layered (deep) structures. The core idea is to propagate input forward through the transformations of the hidden layers in order to get an output.

Training the model

It is impossible to compute the perfect weights for a neural network. Instead learning becomes an optimization problem and algorithms are used to run through the space of possible weights that the model can use to make a good prediction.

Figure: Training is an optimization problem: minimizing loss function

- Training consists of iteratively adjusting the weights in order to minimize a loss function.
- Neural network models are typically trained using the *gradient descent* optimization algorithm and weights are updated using the backpropagation (of error) algorithm

Figure: Currently there seems to be no upper limit on performance - except for the perfect classifier

Loss function

Mean squared error loss:

$$MSE = \frac{1}{n} \sum_{i=1}^n (y_{true} - y_{pred})^2$$

- a good prediction lowers loss \rightarrow training a network \sim trying to minimize loss
- iow: a loss function maps the networks output onto the “loss” associated with a prediction \sim evaluated how well the neural network captures the data structure

CENTER FOR HUMANITIES
COMPUTING AARHUS

If the goal is to minimize loss of the network, the loss is a function of weights w and biases b . For a fully connected one-layered feedforward network ($2 \times 2 \times 1$) then:

$$L(w_1, w_2, w_3, w_4, w_5, w_6, b_1, b_2, b_3)$$

Modifying w_1 then, will change L as $\frac{\partial L}{\partial w_1}$. Using the chain rule:

$$\frac{\partial L}{\partial w_1} = \frac{\partial L}{\partial y_{pred}} \times \frac{\partial y_{pred}}{\partial w_1}$$

Assume a simple binary classifier, $True : 1$, $MSE = (1 - y_{pred})^2$, then:

$$\frac{\partial L}{\partial y_{pred}} = \frac{\partial (1 - y_{pred})^2}{\partial y_{pred}} = -2(1 - y_{pred})$$

For $\frac{\partial y_{pred}}{\partial w_1}$, let h_1, h_2, o_1 be the output of the neurons they represent, then:

$$y_{pred} = o_1 = f(w_5 h_1 + w_6 h_2 + b_3)$$

where f is the sigmoid activation function.

Because w_1 only modulates h_1 and not h_2 :

$$\frac{\partial y_{pred}}{\partial w_1} = \frac{\partial y_{pred}}{\partial h_1} \times \frac{\partial h_1}{\partial w_1}$$

and with the chain rule:

$$\frac{\partial y_{pred}}{\partial h_1} = w_5 \times f'(w_5 h_1 + w_6 h_2 + b_3)$$

Repeat procedure for $\frac{\partial h_1}{\partial w_1}$:

$$h_1 = f(w_1 x_1 + w_2 x_2 + b_1)$$

$$\frac{\partial h_1}{\partial w_1} = x_1 \times f'(w_1 x_1 + w_2 x_2 + b_1)$$

Compute the derivative of the sigmoid function:

$$f(x) = \frac{1}{1 + e^{-x}}$$

$$f'(x) = \frac{e^{-x}}{(1 + e^{-x})^2} = f(x) \times (1 - f(x))$$

Put it all together and we can compute:

$$\frac{\partial L}{\partial w_1} = \frac{\partial L}{\partial y_{pred}} \times \frac{\partial y_{pred}}{\partial h_1} \times \frac{\partial h_1}{\partial w_1}$$

as:

$$-2(1 - y_{pred}) \times w_5 \times f'(w_5 h_1 + w_6 h_2 + b_3) \times x_1 \times f'(w_1 x_1 + w_2 x_2 + b_1)$$

BACKPROPAGATION The system of computing the partial derivatives by working backwards. Backpropagation in this form was derived by Stuart Dreyfus in 1962.

Architectures

Training with Backprop

The most widely used training algorithm is *Stochastic Gradient Descent*, which is a set of formal steps for modifying weights and biases to minimize loss:

$$w_1 \leftarrow w_1 - \eta \frac{\partial L}{\partial w_1}$$

where the learning η rate controls the speed of training

- if $\frac{\partial L}{\partial w_1}$ is positive, then w_1 will decrease and L decrease
- if $\frac{\partial L}{\partial w_1}$ is negative, then w_1 will increase and L decrease

Algorithm 1 Gradient Descent

```
1: while  $t < \text{maxiter}$  do  
2:   for all  $i, j$  do  
3:      $w_{ij} = w_{ij} - \eta \frac{\partial L}{\partial w_{ij}}$   
4:   end for  
5: end while
```

Underlying AI is just rather “dumb” system that improves its performance on a pre-specified task over time by **recursively sending the output of its computations backwards to the parent.**
